Replication of Stock & Inglis (2019): The Longer-Term Labor Market Impacts of Paid Parental Leave

Helen Hoyos

ECON 6693

Master's Research Project

August 4, 2025

Introduction

The main research question of the paper is what are the longer-term labor market impacts of California's Paid Family Leave (CA-PFL) law, particularly on employment, labor force participation, unemployment duration, and earnings, and how do these impacts differ by education level?

This experiment highlights both benefits and costs of California's Paid Family Leave (CA-PFL). On the positive side, the policy improved parent child bonding and caregiving opportunities without adverse effects on less-educated women, while also reducing employee turnover and increasing job continuity for some workers. However, it also led to a 1–2 percentage point decline in employment and a 2–3 percentage point drop in labor force participation among young, college-educated women. Additionally, the benefits were unevenly distributed, favoring more educated individuals, and the policy may have inadvertently caused employers to become more reluctant to hire women of childbearing age.

Data and Replication Approach

The research uses individual-level data from the Current Population Survey (CPS), specifically the Annual Social and Economic Supplement (ASEC) and the Basic Monthly CPS files, covering the years 1996 to 2016. This 20-year span allows the authors to observe labor market trends before and after the implementation of California's Paid Family Leave law in 2004.

The study focuses on several key labor market outcome variables to evaluate the long-term effects of California's Paid Family Leave law. These include labor force participation (whether the individual is actively in the labor force), employment status (currently employed or not), usual weekly hours worked (a measure of labor supply intensity), and annual labor earnings (total earned income from employment over the previous year). These outcomes capture both extensive (participation, employment) and intensive (hours, earnings) margins of labor supply and are used to assess the law's impact on women's labor market behavior over time.

To isolate the policy effect, the researchers performed several data cleaning and transformation steps. They restricted the sample by age to define treatment (18–34) and

comparison (50–64) groups, and by geography, focusing on California as the treated state and excluding other states that had similar paid leave policies prior to 2004. The data were stratified by gender and education level to examine heterogeneous impacts. Additionally, interaction terms were constructed for difference-in-differences (DD) and triple-difference (DDD) models. The analysis also applied appropriate CPS sampling weights to ensure that estimates were nationally representative and comparable over time.

Attempts were made to replicate three key models from the study: **Equation (1): Across-State Difference-in-Differences (DDA)**, **Equation (2): Within-State Difference-in-Differences (DDW)**, and **Equation (3): Triple-Differences (DDD)**. Equation (1) examines how outcome variables such as labor force participation, employment status, and the log of annual earnings differed between California and comparison states before and after the policy. Equation (2) builds on this by comparing young adults (ages 18–34) with older adults (ages 50–64) within each state. Equation (3) integrates both geographic and age group comparisons to isolate the causal effect of the policy, controlling state, age group, and timeframe. This final model, the triple-differences specification, serves as the primary framework for estimating the treatment effects of California's Paid Family Leave law. All regressions include individual level controls for age, age squared, education, U.S. citizenship, race/ethnicity (Hispanic, white, and Black), marital status, presence of children under 5, metro area status, family size, and number of own children in the household. Earnings regressions additionally control for occupation, industry, firm size, usual hours worked per week, and weeks worked last year.

Equation (1): Across-state DD (DDA):

$$Y_{ijt} = B_0 + B_1\left(PPL_j * Post_t\right) + \gamma_1 X_i + 0_1 S_j + 0_2 T_t + e_{ijt}$$

Where:

- T_{ijt}: Outcome variable (labor force participation, employment status, unemployment duration, or log earnings).

- PPL_j: Dummy = 1 if an individual is in California (treatment state).

- $Post_t$: Dummy = 1 for the years after 2004 (post-law period).

- X_i: Control variables (age, education, race, marital status, children under 5, etc.).

- S_j, T_t: State and year fixed effects.

Equation (2): Within-state DD (DDW):

$$Y_{ijt} = B_0 + B_1(Treat_i * Post_t) + B_2 Treat_i + \gamma_1 X_i + 0_1 T_t + e_{ijt}$$

Where:

-$Treat_i$: Dummy=1 if individual is in the young group (ages 18-34), or 0 for older group (50-64).

Equation (3): Triple-Differences (DDD)

$$Y_{ijt} = B_0 + B_1\left(PPL_j * Treat_i * Post_t\right) + B_2 Treat_i + B_3\left(PPL_j * Treat_i\right) + B_4(Treat_i * Post_t) + \gamma_1 X_i + 0_1 S_j + 0_2 T_t + 0_3\left(S_j * T_t\right) + e_{ijt}$$

Where:

-$PPL_j * Treat_i * Post_t$: Key interaction term measuring CA-PFL impact on young individuals in California.

-B_1:Main coefficient of interest (Average Treatment Effect on the Treated).

Replication Results: Summary Statistics

The summary statistics for both females and males from the replication closely align with the values reported in the research. For females, labor force participation, employment status, weeks unemployed, and log annual earnings were consistent across all subgroups: California and comparison states, both pre- and post-policy, and across age groups (18–34 and 50–64). For example, labor force participation among California women aged 18–34 remained steady at 0.64 before and after the policy, while employment slightly declined from 0.92 to 0.90. These values match those reported in the original research, confirming the reliability of the reproduced data.

Outcome Variable Summary Statistics: Females

	California				Comparison States			
	Treatment age group (ages 18–34)		Comparison age group (ages 50–64)		Treatment age group (ages 18–34)		Comparison age group (ages 50–64)	
	Pre-CA-PFL	Post-CA-PFL	Pre-CA-PFL	Post-CA-PFL	Pre-CA-PFL	Post-CA-PFL	Pre-CA-PFL	Post-CA-PFL
In Labor Force	0.64 (0.48)	0.64 (0.48)	0.56 (0.50)	0.59 (0.49)	0.72 (0.45)	0.69 (0.46)	0.60 (0.49)	0.64 (0.48)
Employed	0.92 (0.27)	0.90 (0.30)	0.95 (0.22)	0.93 (0.25)	0.93 (0.25)	0.92 (0.27)	0.97 (0.17)	0.96 (0.20)
Weeks Unemployed	5.2 (1.2)	5.1 (1.3)	4.4 (1.1)	4.3 (1.0)	5.3 (1.3)	5.0 (1.2)	4.5 (1.0)	4.4 (0.9)
Log Annual Earnings	10.2 (0.45)	10.3 (0.50)	10.4 (0.40)	10.5 (0.43)	10.1 (0.48)	10.2 (0.47)	10.3 (0.41)	10.4 (0.42)

Similarly, the male summary statistics mirrored the research exactly. Labor force participation, employment rates, weeks unemployment, and log earnings were consistent across all subpopulations. For instance, labor force participation for young California males declined from 0.85 pre-policy to 0.78 post-policy, while their employment rate dropped from 0.94 to 0.91 values that directly match those in the published table. This consistency in both female and male tables validate the accuracy of the reproduced summary statistics and affirms that the extracted data is an accurate reflection of the original source.

Outcome Variable Summary Statistics: Males

	California				Comparison States

The outcomes reported in Table 1 are consistent across both the replication and the published paper. For young females, both sources indicate that California's Paid Family Leave (PFL) law had minimal impact on labor force participation and earnings, with a very small positive effect on employment and a modest reduction in unemployment duration. Specifically, the employment effect is slightly positive (approximately +0.0083 in the replication and +0.006 in the paper), while labor force participation remains essentially unchanged. Similarly, weeks unemployed are reduced slightly, and the impact on the log of annual earnings is near zero. For young males, the results also align between the two outcomes: the PFL law has no significant effect on labor force participation, a small positive effect on employment, and a notable reduction in unemployment duration (around −0.6457). The earnings effects for young males are small and statistically insignificant in both the replication and paper. Overall, Table 1 results are nearly identical in size and direction, indicating minimal to moderate labor market impacts of the PFL policy when comparing California to all other states.

Table 2: Difference-in-Differences Estimates – Younger vs. Older in California

TABLE 2: Difference-in difference estimates: Younger v. older in California

Outcome	Females	Males
In Labor Force	-0.0406*** (0.003)	-0.0048*** (0.002)
# of obs.	378,804	341,087

# of obs.	378,804	341,087
R-squared	0.452	0.41

The estimates in Table 2 from the replication precisely match those found in the published paper. These within California comparisons show that young women experienced declines in labor force participation and employment relative to older women following the implementation of the PFL law. The coefficients for labor force participation are strongly negative, ranging from −0.0406 to −0.118, and employment declines range from −0.0329 to −0.0205. Additionally, weeks unemployed increased for young females, with point estimates up to +1.7 weeks, although some of these estimates are not statistically significant. Log earnings also declined sharply for young women compared to older women, with estimates ranging from −1.7 to −3.9. A similar pattern is seen among males, though the effects are smaller in size. Young males experienced slight declines in labor force participation and employment, slight increases in unemployment duration, and reductions in log earnings. These results suggest that employers may have substituted away from younger workers toward older workers after the PFL law was passed.

R-squared	*0.108*	*0.051*	*0.081*	*0.212*

In contrast to Tables 1 and 2, the DDD results in Table 3 differ between the replication and paper. In the replication, the DDD estimates suggest a small and positive effect of the PFL law on employment and weeks unemployed for both young females and males. For example, the female employment effect is reported as 0.004 (statistically significant), while for males it is 0.0064. These findings suggest minor labor market improvements post-PFL for younger workers. However, the published paper finds a different result, it finds a negative and statistically significant employment effect for young females (−0.008) and a substantial reduction in weeks unemployed for young males (−0.775), which contradicts the replication results. Additionally, the paper reports no significant effects on labor force participation or earnings for either gender. The differences in Table 3 from the paper may be due to differences in weighting or how groups were defined in the replication.

Discussions and Reflection

Through this replication, we learned that sample restrictions and data cleaning are critical to accurately reproducing research results. Even minor discrepancies in filtering by age, geography, or timeframe can significantly affect outcomes. We also discovered the importance of time management, especially when working with complex datasets and statistical models.

Additionally, understanding the sample size and population structure proved essential for interpreting the authors' intent and contextualizing the research findings.

If starting over, we would first aim to gain a deeper understanding of how the authors applied weighting and clustering techniques in their models, as these choices influence both estimation and inference. We would also thoroughly review the entire research methodology upfront before replicating, to ensure a clearer roadmap and avoid unnecessary trial and error during the process. This would help streamline the workflow and improve the accuracy and efficiency of the replication.
